

Homebrew Setup

Homebrew Setup

Homebrew is the package manager for macOS used to install all development dependencies in this project.

Check if Homebrew is already installed

Open a terminal and run:

```
brew --version
```

If a version number is printed, Homebrew is already installed. Skip the installation step below.

Installation

If the command above returns `command not found`, install Homebrew by running:

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
```

The script will guide you through the process. It may prompt for your macOS password.

Post-installation (Apple Silicon only)

On M1/M2/M3 Macs, add Homebrew to your shell path after installation:

```
echo 'eval "$(/opt/homebrew/bin/brew shellenv)"' >> ~/.zprofile  
file  
eval "$(/opt/homebrew/bin/brew shellenv)"
```

Verify it works:

```
brew --version
```

Notes

- Intel Macs install Homebrew to `/usr/local`. Apple Silicon Macs use `/opt/homebrew`.
- Keep Homebrew up to date with `brew update && brew upgrade`.
- If you run into permission errors during install, do not use `sudo` — the installer handles permissions on its own.
