

Redis Setup

Redis Setup

Redis is used as an in-memory store for caching, session management, and handling fast key-value lookups.

Installation

Install Redis

```
brew install redis
```

Start the Redis service

```
brew services start redis
```

Install RedisInsight (GUI client — recommended for monitoring keys, memory usage, and running commands visually)

```
brew install --cask redis-insight
```

Verify the connection using the CLI

```
redis-cli
```

Requirements

Component	Type	Notes
redis	Required	Core in-memory data store
redis-cli	Required	Included with the install; used to verify the connection
redis-insight	Good to have	Not strictly required to run the app, but useful for inspecting keys, monitoring performance, and debugging cache issues

Notes

- Run `brew services list` to confirm Redis is active.
- RedisInsight connects to `localhost:6379` by default.
- Test the connection inside `redis-cli` by running `PING` — a response of `PONG` means everything is working.
